ABSTRACT

A long cycle of adaptation is going on in the ecosystem either it is a human being who adapted or a plant. Recently carnivorous plants have taken the stage of adaptation. By not getting photosynthesis and nitrogen from the environment non carnivorous plants have adapted to carnivorous species. Researchers have discovered thousands of new species of carnivorous plants. Recently the social network photographs have revealed the third largest species of Droserea family that is Drosera magnifica. In this article, we have discussed Drosera magnifica, its discovery, habitat and its future prospects in relation to its phytochemistry and pharmacology.

Keywords: Carnivorous, Droseraceae, Drosera magnifica, Phytochemistry, Pharmacology.

INTRODUCTION

Herbalism has evolved independently in therapeutic world. The thirst of finding new star in the herbarium solar system is still going on. Now researchers have gone through the plants that feed on human flesh and blood ¹. Botanical Carnivorous plants survive nutrient poor habitat which trap and utilize tiny animals. They do not even bear true roots instead leaves are modified to accommodate a trap function on either aerial or underground/submersed parts. Animals are caught by traps formed by highly specialized metamorphous leaves². Root porosity and root depth were quantified in eight carnivorous plant species and 48 non-carnivorous species within a nutrient-poor wet pine savanna in south Mississippi, USA³. Carnivorous and non-carnivorous plant species were contrasted with respect to their indication of wetlands, open habitats, and habitats with nutrient-poor soil that is Carnivorous plants have adapted to grow in places where the soil is thin or poor in nutrients, especially nitrogen, such as acidic bogs and rock outcroppings³. In 1860 Charles Darwin found how insects were caught by plants and in 1875 he wrote Insectivorous Plants ⁴, the first well-known treatise on carnivorous plants. No carnivorous plant is able to capture prey by its flower. Givnish et al. (1984) proposed that a plant must fulfil two basic requirements to be considered as carnivorous⁵. First, it must be able to absorb nutrients from dead prey, and thereby obtain some increment to fitness in terms of increased growth, pollen production or seed set. Secondly, the plant must have some adaptation or resource allocation whose primary result is the active attraction, capture and/or digestion of prey. Many plants can passively profit by absorbing some nutrients from dead animals decomposing in the soil or on leaf surfaces ⁶,⁷. A plant must have at least one adaptation (i.e. active attraction, capture and digestion) in combination with nutrient absorption to be qualified as carnivorous, because many genera of carnivorous plants lack some of these attributes. Likewise, Drosera magnifica is the carnivorous plant that belongs to the largest carnivorous genus Drosera. The plant was discovered and
authenticated by the botanists Paulo Minatel Gonella, Fernando Rivadavia & Andreas Fleischmann and subsequently the plant was reported in the Phytotaxa journal1.

Evolution:
Carnivore evolved as a method to increase nutrients in extremely nutrient poor conditions, leading to a cost-benefit model for botanical carnivory. 8,12 Cost-benefit models are given under the assumption that there is a set amount of energy potentially available for an organism, which leads to trade-offs when energy is allocated to certain functions to maximize competitive ability and fitness10,24,30. Most carnivorous plants live in habitats with high light, waterlogged soils, and extremely low soil nitrogen and phosphorus, producing the ecological impetus to derive nitrogen from an alternate source. High light environments allowed tradeoff between photosynthetic leaves and prey capturing traps that are photosynthetically inefficient. To compensate for photosynthetically inefficient material, the nutrients obtained through carnivory would need to increase photosynthesis by investing in more leaf mass11,13,15. This means when there is a shortage of nutrients and enough light and water, prey capture and digestion has the greatest impact on photosynthetic gains, favoring the evolution of plant adaptations which allowed for more effective and efficient carnivory14,20,26&28. Due to the large amount of energy and resources allocated to carnivorous adaptations, i.e. the production of lures, digestive enzymes, modified leaf structures, and the decreased rate of photosynthesis over total leaf area, some authors argue that carnivory is an evolutionary last resort when nitrogen and phosphorus are limited in an ecosystem. All trap types are modifications of a similar basic structure—the hairy leaf16, 17,18. Hairy (or more specifically, stalked-glandular) leaves can catch and retain drops of rainwater, especially if shield-shaped or peltate, thus promoting bacteria growth. The active glue traps use rapid plant movements to trap their prey. Rapid plant movement can result from actual growth or from rapid changes in cell turgor, which allows cells to expand or contract by quickly altering their water content. Slow-moving flypapers like Pinguicula exploit growth, while the Venus flytrap uses such rapid turgor changes which make glue unnecessary. The stalked glands that once made glue became teeth and trigger hairs in Drosera—an example of natural selection hijacking preexisting structures for new functions19,22&24.

Trapping mechanism of Carnivorous plants:
Five basic trapping mechanisms are found in carnivorous plants21,27,29&30.
1. Pitfall traps (pitcher plants) trap prey in a rolled leaf that contains a pool of digestive enzymes or bacteria.
2. Flypaper traps use sticky mucilage.
3. Snap traps utilize rapid leaf movements.
4. Bladder traps suck in prey with a bladder that generates an internal vacuum.
5. Lobster-pots, also known as eel traps, force prey to move towards a digestive organ with inward-pointing hairs.

These traps may be active or passive, depending on whether movement aids the capture of prey. For example, Triphysophyllum is a passive flypaper that secretes mucilage, but whose leaves do not grow or move in response to prey capture21,25.

Physiology of carnivorous activity of Drosera:
Leaves have club shaped hair on their upper surface called tentacles. Tentacles have expanded reddish tips which secrete sticky, purple colored juice which sparkle in the sun like dew drops which helps to attract the insects to the shiny drop. This is the only reason why this plant is called as sun dew. When an insect comes in the contact with the leaf tentacle, the leaf starts secreting as the tentacle is sensitive to the protein body and the insect get trapped in the sticky fluid and the tentacle starts bending. The process is supported by bending and folding of leaf margins to form cup-like structure. Entrapped insects are digested by fluid which contains the protease enzyme that breaks the insect body proteins into amino acids. These amino acids are absorbed and consumed by the plants for the synthesis of proteins.10,27,28 Recently a very interesting and new kind of interaction between insects and carnivorous plants has been reported from Brazil. Larvae of the predatory flower fly Toxomerus basalis have been found scavenging on the sticky leaves of several carnivorous sundew species. This hoverfly apparently spends its larval stage feeding on prey trapped by Drosera leaves30.

Classification of carnivorous plants:
The classification of all flowering plants is currently in a state of flux. In the Cronquist system, the Drosoraceae and Nepenthaceae were placed in the order Nepenthales, based on the radial symmetry of their flowers and their possession of insect traps. The Sarraceniaceae was placed either in the Nepenthales, or in its own order, the Sarraceniales. The Byblidaceae, Cephalotaceae, and Roridulaceae were placed in the Saxifragales; and the Lentibulariaceae in the Scrophulariales (now subsumed into the Lamiales)31,32,47.

In more modern classification, such as that of the Angiosperm Phylogeny Group, the families have been retained, but they have been redistributed amongst several disparate orders29. The family Drosoraceae is usually supposed to contain four genera, Drosophyllum, Dionaea, Aldrovanda and Drosera, of which the first three are mono- typic and the fourth, Drosera, has about 125 species33,24,35. The current recommendations is shown in Table:1 (only carnivorous genera are listed):

**Droseraceae (Sundew family):**

Charles Darwin, who discovered the carnivorous nature of other Drosera species, wrote: “At this present moment I care more about Drosera than the origin of all the species in the world”. Droseraceae is a small family of mostly herbaceous plants, all remarkable for the glandular hair with which they catch insects. These insectivorous herbs secrete enzymes to digest the tissues of insects and often lack chlorophyll. The main chemical constituents present in Droseraceae are flavonoids, quinines and other constituents such as carotenoids, resins, tannins, ascorbic acid. **Drosera magnifica:**

Scientist Paulo Gonella made a brilliant discovery while scrolling through Facebook. *Drosera magnifica* is considered as the first new plant species “discovered” on the social network. A botanist Reginaldo Vasconcelos posted a photo of the plant in 2012 while trekking near his home in southeastern Brazil. After a year, Gonella confound across the photograph when another friend of his reposted it on Facebook. Gonella, a plant researcher at the Institute of Biosciences at the University of São Paulo noticed this species of Drosera was new. The plant in the photo seemed totally dissimilar from all the other species. Gonella told Smithsonian.com via Facebook Messenger. Soon, Gonella and Vasconcelos went back to the mountain and confirmed that the plant, *Drosera magnifica*, was in fact new discovery in the field of science, figure: 1, represents image of the plant. After examining the plant along with other researchers at the Botanical State Collection in Munich, they declared its discovery in the journal *Phytotaxa*. 36
It is a species of sundew, endemic to Pico Padre Ângelo (1500–1530 m asl) in eastern Minas Gerais in southeastern Brazil, where it grows among sandstone outcrops in herbaceous and shrubby vegetation. It is one of the three largest species of *Drosera* - the other two being *D. regia* from South Africa and *D. gigantea* from Australia. It is the largest New World sundew, and it is closely related to *Drosera graminifolia* and *Drosera spiralis*. The genus *Drosera* presents a worldwide distribution with about 250 species and is currently considered the largest carnivorous plant genus.

Paul A. Egan, 2013, have discussed in his review article about producing lead compounds from the *Drosera* to treat tuberculosis and potential role of anthocyanins in nitrogen transport. This article relates *Drosera magnifica* with other closely related species so that *Drosera magnifica* can be utilized properly for its potential medicinal activities. 8-hydroxy-luteolin-8-O-arabinopyranoside, tricetin-7-O-xylopyranoside and 8-hydroxytricetin-8-O-arabinopyranoside were the constituents that were described for the first time using LC-DAD-MS, LC-NMR, and offline 1D and 2D NMR analyses and around 40 different ambiguous substances were also identified. Closely related species to *Drosera magnifica* are rich in flavonoids, quinines, naphthoquinones and other constituents such as carotenoids, resin, tannins, ascorbic acid etc. If screened systematically we cannot rule out the presence of common chemical constituents in *Drosera magnifica*.

Table 2: Represents the common chemical constituents that are found in the related species of *Drosera magnifica*.

Based on the chemical constituents, there are some common pharmacological properties of species related to Drosera magnifica:

1) Antioxidant activity:
Due to the presence of good amount of flavonoids and quinines the plant would possess high antioxidant activity62.

2) Inflammation:
As Drosera rotundifolia possesses good anti-inflammatory activity due to the presence of flavonoids. Drosera magnifica is also prone to possess anti-inflammatory mechanisms via their ability to inhibit reactive oxygen or nitrogen compounds63-67.

3) Cancer:
Dietary flavonoid intake is associated with reduced gastric carcinoma risk in women, and reduced aero digestive tract cancer risk in smokers. So there may be chances that Drosera magnifica can be used to reduce carcinoma risk due to presence of both quinines and flavonoids67,71.

4) Cardiovascular disease:
Flavonoids have the property to treat cardiovascular diseases, so the presence of good amount of flavonoids in Drosera genus hints that Drosera magnifica may have the following actions51-77:
- inhibit coagulation, thrombus formation or platelet aggregation
- reduce risk of atherosclerosis
- reduce arterial blood pressure and risk of hypertension
- reduce oxidative stress and related signaling pathways in blood vessel cells
- modify vascular inflammatory mechanisms
- improve endothelial and capillary function
- modify blood lipid levels
- regulate carbohydrate and glucose metabolism
- modify mechanisms of aging

5) Antimicrobial Activity:
Drosera magnifica may also have direct antibacterial activity, synergistic activity with antibiotics, and the ability to suppress bacterial virulence factors in numerous in vitro and a limited number of in vivo studies due to presence of flavonoids and Quinones77,78,79.

6) Biochemistry:
Derivatives of quinones are common in biologically active molecules as an electron acceptor as well as for production of useful metabolites in aerobic respiration. Hence Drosera magnifica may be used for production of various metabolites in biochemistry80-83.

7) Dying Agent:
Due to presence of quinines Drosera magnifica may be used as natural dyes84.

8) Antispasmodic effects:
D. Madagascariensis having flavonoid is said to affect the M1 muscarinic receptors in smooth muscle, causing the antispasmodic effects so D. magnifica is prone to show antispasmodic activity as well85-90.

9) Antiangiogenic effects
Ellagic acid present in D. rotundifolia possess antiangiogenic activity so D. magnifica may be properly utilized for the screening of antiangiogenic activity91.

10) Nanotechnology:
The mucilage produced by Drosera has remarkable elastic properties and has made this genus a very attractive subject in biomaterials research. In one recent study, the adhesive mucilage of three species D. binata, D. capensis and D. spatulata were analyzed for nano fiber and nanoparticle content92,93,94. So D. magnifica, if utilized properly can lead its way in novel drug delivery aspects.

11) Miscellaneous uses:
D. rotundifolia, D. anglica and D. linearis as being used as stimulants and expectorants, hence D. magnifica may be used for treating bronchitis, whooping cough, and tuberculosis95. Also due to the presence of tannins/resins D. magnifica may be used for varnishes, adhesives, colouring, as well as various therapeutic activities.

DISCUSSIONS
As there is no systematic literature available of this newly discovered plant our article will provide directions to the scientists based on the scientific rationale so that the plant should be properly utilized in the field of medicine. IUCN has mentioned Drosera magnifica as critically endangered species so it is our duty to study this plant more carefully in regard to conserving its habitat and proper utilization. Species of carnivorous genus Drosera have long been used as a source of potent products. We didn’t have substantial literature of Drosera magnifica, in treating various diseases so this article provides a bridge between Drosera magnifica to the various other closely related species. Rich constituents like flavonoids, quinines, naphthoquinones, resin, tannins are widely found in the genus Drosera that have potent medicinal values and there is high probability of finding these constituents in Drosera magnifica as well according to the literature we surveyed.

CONCLUSION
The present study gives a mind opening view on Drosera magnifica that how this plant can be utilized in treating health ailments based on the probability of the various chemical constituents that may be present in it. It gives the scientists a chassis as well as direction to research this newly discovered plant for its pharmacological activities so that the plant can make its
way into the pharmaceutical industry in a much more constructive way.

Summary:

- *Drosera magnifica* a new species of Droseraceae family.
- *D. magnifica* may be rich in flavonoids, quinines and other constituents such as carotenoids, resin, tannins, ascorbic acid.
- *D. magnifica* may be having anti-inflammatory, antispasmodic, antibacterial, anti-tumor activity.
