ABSTRACT

Fast-dissolving oral films have emerged as alternative dosage forms for the patients who experience difficulties in swallowing traditional oral solid dosage forms such as tablets, capsules, and syrups etc. These dosage forms disintegrate or dissolve very quickly within seconds when placed in the mouth cavity without need of water or chewing. Due to fast dissolution it provide faster onset of action, bypassing the first pass metabolism, reducing gastric degradation and metabolism of drugs and thus enhance their oral bioavailability. These properties of oral films with patient convenience and compliance made popular and accepted dosage form for pediatric and geriatric as well as adult population. These formulations are suitable for cough, cold, sore throat, allergenic conditions, nausea, pain, hypertension and CNS disorders, epilepsy and many more diseases. The present review provides up to date review in fast dissolving oral films in tabular form so researches can easily track various technologies/research in design and development of oral fast dissolving film.

Keywords: Mouth dissolving films, Oral dispersible film, Oral dissolving film, Oral disintegrating film.

1. INTRODUCTION

Oral route is a most preferred route of drug administration for systemic effect due to its ease of administration, non-invasiveness, adaptability, patient compliance and acceptability1,2. Tablet is the most preferred dosage form due to ease of manufacturing, transportation and more patient compliance3. Generally geriatric, pediatric, nauseous, bed ridden and non-compliance patients experience difficulties in swallowing the conventional oral dosage form and do not take their medicines as prescribed. It is estimated that 50% of the population was affected by this problem, which finally results in a higher chance of non-compliance & ineffective therapy4.

The elderly constitute a major portion of today’s population mainly because of increased life expectancy of individuals5. Dysphagia or difficulty in swallowing is common problem, this disorder is coupled with several medical conditions including stroke, AIDS, thyroidectomy, Parkinson’s disease, head and neck radiation therapy and other neurological disorders as well as encephalopathy6. The most common complaint with tablet is size, fear of choking. The problem of swallowing tablets is more evident in geriatric and pediatric patients, as well as travelling patients who may not have ready access to water7.

To overcome this Oral fast disintegrating drug delivery systems were developed, these systems were initially developed within the late Seventies as an alternative to tablets, capsules and syrups for pediatric & geriatric patients who experience difficulties in swallowing traditional oral solid dosage forms. These dosage forms either dissolve or disintegrate generally within a 3 minute in mouth, without need of water. Oral fast Disintegrating dosage form have started gaining popularity & acceptance as new drug delivery system due to better patient compliance8.
Oral fast disintegrating dosage form consists of mouth dissolving tablets & fast dissolving films. Mouth dissolving tablets associated with many problems like leave residues in mouth which causes feeling of grittiness in mouth; there is a fear of choking, difficulty in swallowing tablets. To beat the issues of mouth dissolving tablets, a new drug delivery system for the oral delivery of the drugs, was investigated which is known as Fast dissolving films/oral dispersible film/mouth dissolving films / oral disintegrating film/oral dissolving film.

Fast dissolving oral film was developed based on the technology of the transdermal patches for oral delivery of drugs. The delivery system consists of a thin film of the size of a postage stamp, which is placed on the patient’s tongue or mucosal tissue, where it instantly hydrates by absorbing saliva; the film then rapidly disintegrates and dissolves to release the drug for oral mucosal absorption. This fast dissolving action is primarily due to the large surface area of the film, which wets quickly when exposed to the moist oral environment.

1.1 Special features of fast dissolving oral films

- Thin elegant film
- Available in various size and shapes
- Unobtrusive
- Excellent mucoadhesion
- Fast disintegration and dissolution
- Rapid drug release
- Bypasses first pass effect

1.2 Advantage of orally fast dissolving oral films

- No need of water for administration.
- Convenient for pediatric, geriatric and dysphasic patients having difficulty in swallowing.
- Rapid disintegrating and dissolution in the oral cavity due to larger surface area of films.
- Rapid onset of action with increased bioavailability due to bypassing hepatic first pass effect.
- Reduce dose, enhances the efficacy and safety profile of the drug with reduced side effects.
- Flexible and portable in nature so they provide ease in handling, transportation and storage.
- Ease of administration to mentally ill, disabled, uncooperative patients and the patients who are on reduced liquid intake plans or are nauseated.
- Beneficial in cases such as motion sickness, acute pain, sudden allergic attack, asthmatic attack and coughing, where an ultra rapid onset of action is required.
- Stability for longer duration of time, since the drug remains in solid dosage form till it is consumed.
- Accuracy in dose as compared to liquid formulations.
- Pleasant mouth feel, leave negligible or no residue in the mouth after administration.

1.2 Limitations of fast dissolving oral films:

- High doses cannot be incorporated.
- Excessive bitter drugs are not feasible.
- Dose uniformity is a technical challenge.
- They require special packaging for the products stability and safety.
- Drugs which irritate the oral mucosa cannot be administered by this route.

2. Formulation of fast dissolving films: - Fast dissolving Oral films include various ingredients for its formulation such as

- Active pharmaceutical ingredient
- Film forming polymers
- Plasticizer
- Sweetening agent
- Saliva stimulating agent
- Surfactants
- Flavoring agent
- Coloring agent

2.1 The ideal characteristics of drug to be selected

- The drug should have pleasant taste.
- The therapeutic dose of the drug should not be greater than 40mg.
- The drug should have small molecular size and low molecular weight.
- The drug should have good solubility and stability in water as well as in saliva.
- It should be partially ionized at the pH of oral cavity.
- The drug should exhibit low sensitivity to environmental conditions.
- It should have the ability to permeate oral mucosal tissue.

2.2 Film Forming Polymers

Polymer is the major and most essential component of FDOFs. A variety of polymers are available for preparation of oral film and these are used in the concentration of about 40-45% w/w of total film weight but can be increased up to 65% w/w of film weight alone or in combination to obtain desired properties of oral film. The film obtained should be tough enough so that there may not be any damage while handling or during transportation. The robustness of the film depends on the type of polymer and the amount in the formulation. The physicochemical characteristic of the polymer or polymers selected for film formulation play a vital role in determining the resultant disintegration time of the prepared film.

2.3 Ideal properties of the film forming polymers

- The polymer employed should be non-toxic, nonirritant and devoid of any leachable impurities.
- It should be tasteless.
- It should have good wetting and spread ability property.
- The polymer should exhibit sufficient peel, shear and tensile strengths.
- The polymer should be cheap and readily available.
- It should have long shelf life.
- It should not cause any secondary infections in the oral mucosa/dental region.
- It should have a good mouth feel property.
- It would be ideal to have a polymer that would have local enzyme inhibition action along

2.4 Manufacturing Methods

One or combination of the following process can be used to manufacture the mouth dissolving films:

- i) Solvent casting
- ii) Semisolid casting

Kumar et al., (2013) Formulation development and in vivo evaluation of zolmitriptan oral dissolving films. Zolmitriptan oral dissolving films were prepared for migraine treatment using different grades of HPMC E3, E6 and E15, Maltodextrin DE6 and Xanthan gum as polymers. Citric acid as saliva stimulating agent, propylene glycol as plasticizer, aspartame as artificial sweetener and vanillin as flavouring agent by solvent casting technique. The optimized formulation prepared using HPMC E15 showed minimum disintegration time (10 sec), highest dissolution rate i.e. 99% of drug within 8 min and satisfactory physicochemical properties.

Patel et al., (2013) Development and optimization of fast dissolving film of losartan potassium Fast dissolving films of losartan potassium were prepared for the treatment of hypertension. The fast dissolving films were prepared by the solvent casting technique. Films were evaluated for drug content and the drug loading capacity. The best formulation containing 250 mg HPMC-E15, 50 mg HPMC E5, 50 mg MCC and 30 % w/w PEG-400 has lowest disintegration time of 30 sec and released 99.64 % drug in 10 minutes.

Kathpalia et al., (2013) Development and Evaluation of Orally Disintegrating Film of Tramadol Hydrochloride. Asian Journal of biomedical and pharmaceutical sciences Orally disintegrating films of Tramadol Hydrochloride were prepared which disintegrate within 30 seconds. Two polymers such as modified pea starch (Lycoat RS 720) and pullulan were evaluated for film forming capacity and were found to form thin, smooth films at 25% w/w and 2% w/w concentration respectively.

Bansal et al., (2013) Investigation of polymers alone and in combination for the development of oral thin film. Researchers work on different polymers such as Sodium carboxy methyl cellulose ( Na CMC), Hydroxypropyl methyl cellulose(HPMC E15, HPMC E5, HPMC K-15,HPMC K50), soluble starch, pectin, gelatin glycerol and tween 80 alone and in combination for the development of oral thin films. HPMC K15 films alone and in combination were found to have comparatively low folding endurance and tend to produce viscous gel instead of disintegrating and dissolving. Combination of soluble starch with HPMC K15 even in low concentration tend to produce films which were opaque and had poor folding endurance.

Nalluri et al., (2013) Development and evaluation of mouth dissolving films of salbutamol sulfate Mouth dissolving films of Salbutamol Sulfate prepared. Hydroxy propyl Methylcellulose of different viscosity grades as film former, along with film modifer/solubilizing agents, polyvinyl pyrollidone K30 (PVP K30) and sodium lauryl sulphate (SLS) to formulate MDFs. MDFs with 13% w/w of HPMC E5 gave better dissolution properties compared to HPMC E15. The film prepared using HPMC E5 and SLS showed the highest dissolution rate, suitable in vitro disintegration time and satisfactory physico-mechanical properties.

Panchal et al., (2012) Formulation and evaluation of mouth dissolving film of ropinirole hydrochloride by using pullulan polymers. Mouth dissolving films of Ropinirole Hydrochloride for treatment of parkinson’s disease and rest leg syndrome prepared by a solvent casting method with the help of 32 full factorial designs. Mouth dissolving film of Ropinirole Hydrochloride containing pullulan as polymer showed 99.48 ± 0.18 % drug release at 60 sec.

Choudhary et al., (2011) Exploration of film forming properties of film formers used in the formulation of rapid dissolving films Films were prepared by solvent casting method using different grades of methocel, Polyx and natural gums as film formers. Films composed of Pullulan in combination with Xanthan gum have good visual appearance, excellent film forming capacity along with tensile strength 5.56 N/mm2, disintegration time 22 seconds and dissolution time 42 sec.

Mishra et al., (2011) Formulation and characterization of rapidly dissolving films of cetizetine hydrochloride using pullulan as a film forming agent Rapidly dissolving films of cetizintine hydrochloride using pullulan as film forming polymer by solvent casting technique were prepared. It was reported that 5%/w/v pullulan as film former.PEG-400 as plasticizer, aspartame as sweetener (is used to mask the bitter taste of drug) along with passion fruit flavour and citric acid when casted on Teflon base gives excellent transparent films with good physical properties and disintegration and dissolution time within 30 seconds.

Saini et al., (2011) Formulation, development & evaluation of oral fast dissolving anti-allergic film of levo cetizine Fast dissolving film of levo cetizine dihydrochloride by solvent casting method using maltodextrin and HPMC E15 as the film forming polymers were prepared. To decrease the disintegration time, concentration of maltodextrin & HPMC E15 were optimized using 22

Dinge et al., (2008) Formulation and evaluation of fast dissolving films for delivery of triclosan to the oral cavity. Triclosan containing fast dissolving films for local delivery to oral cavity were formulated. Various film forming agents, film modifiers and polyhydric alcohols were evaluated for optimizing the composition of fast dissolving films. The potential of poloxamer 407 and hydroxypropyl-β- cyclodextrin to improve solubility of Triclosan was investigated.

Ali and Quadir, (2007) High molecular weight povidone based films for fast dissolving drug delivery applications. High molecular weight povidone K-90 polymer as a film forming excipient were evaluated for fast dissolving drug delivery applications. It was evaluated in combination with povidone K-30 and other kollidon SR polymers. Fast dissolving films suitable for delivery of highly potent drugs and vitamins could be formulated using the povidone povidone K 90 with auxiliary polymers.

Gohel et al., (2007) Development of taste masked film of valdecoxib for oral use. Oral films of valdecoxib using Eudragit EPO and hydroxy propyl methyl cellulose were developed. Glycerol, menthol and aspartame were incorporated in the drug containing films as plasticizer, cooling agent and sweetener respectively. The drug loading was 10 mg per 4 cm² of the film. The films were evaluated for hydration study, folding endurance and in vitro drug dissolution in the distilled water.

Mashru et al., (2005) Development and evaluation of fast dissolving film of salbutamol sulphate. Fast dissolving films for sublingual route containing salbutamol sulphate and polyvinyl alcohol as polymer were developed and evaluated for mechanical properties, in vitro release study and morphology study. A 3² factorial design was applied to study the effect of polyvinyl alcohol, glycerin and mannitol on % drug release and mechanical properties of the films. It was observed that Mannitol produced positive effect on drug release where as polyvinyl alcohol produced negative effect on drug release.

4. CONCLUSION
The key advantage for fast dissolving oral films is patient compliance and convenience. The main drawback is with drug loading. Drug loading is generally limited to roughly 40 mg. This problem can be solved by increasing the thickness of the film, but that in turn may increase the disintegration and dissolution time. Drug companies are still interested in this technology as it provides fast, accurate dosing that is expected to increase patient compliance, particularly among pediatrics. There is no need for water or measuring devices. The dose of drug is swallowed. Thus we can say that Fast-dissolving oral thin film offer fast, accurate dosing in a safe, efficacious format that is convenient and portable, without the need for water or measuring devices.
