ABSTRACT

Modern drug discovery has led to the development of drug molecules that exhibit high lipophilicity and poor water solubility, which leads to problematic bioavailability. Approaches have thus been made to enhance dissolution of poorly water soluble drugs through modifications and creation of specific formulations. Metaclopramide is an antiemetic and gastroprotective agent, commonly used to treat nausea and vomiting. It is absorbed well after oral administration but a significant first pass effect in some human patients may reduce systemic bioavailability, which can cause adverse side effects. This solid dispersion has then been used through transdermal drug delivery. Enhancement of solubility of poorly water soluble drug by solid dispersion may be attributed to particles modified characters such as particle size reduction, improved wettability, higher porosity, decreased lattice energy, amorphous state. The main objective thus includes modification of drug Metaclopramide hydrochloride to Metaclopramide base, preparation of solid dispersion of modified Metaclopramide base drug which has poor water solubility, experimental analysis of Metaclopramide base drug and solid dispersion products with carriers.

Keywords: solubility, Metaclopramide, solid dispersion, carriers, HPβCD, PVP K-30

INTRODUCTION:

Metaclopramide is chemically 4-amino-5-chloro-N-[2-(diethyl amino)ethy]l]-2-methoxybenzamide. The antiemetic action of Metaclopramide is due to its antagonist activity at D2 receptors in the chemoreceptor trigger zone in the central nervous system and this action prevents nausea and vomiting triggered by most stimuli. The gastroprotective activity is mediated by muscarinic activity, D2 receptor antagonist activity and 5-HT-4 receptor agonist activities. It has a molecular weight of 299.8 and its melting point is 147 degree Celsius.

Enhancement of solubility of poorly water soluble drug can be done by solid dispersion technique. Though there are simple techniques to prepare solid dispersions problems are often encountered, such as physicochemical stability of drug and vehicle, making suitable formulation of solid dispersion of into dosage forms and scale up of process.

Fig. 1: Structure of Metaclopramide

R. Vijaya et, al (2012) expressed that transdermal drug delivery delivers the drug through topical route for systemic effect at a predetermined and controlled rate. In this study, transdermal films of amitriptyline HCl has been formulated using polymers of hydroxypropyl cellulose and polyvinyl
pyrrolidone in different compositions, the films were then evaluated for their physicochemical properties.

Complexation is one such technique of preparing a solid dispersion, wherein the drug is bound to a carrier because of weak Vander Waals forces and it is released from its bound state only when it gets exposed to a suitable chemical environment. In this kind of solid mixture a guest molecule forms complex with an inert soluble carrier (host molecule) in the solid state. One of the most widely used complex carriers is within the class of cyclodextrins[6,7] Cyclodextrins are a family of cyclic oligosaccharides composed of α- (1,4)-linked glucopyranose subunits. It is composed of interior hydrophobic cavity, whereas the exterior is highly hydrophilic. The lipophilic cavity of cyclodextrin molecules provides a microenvironment into which appropriately sized non polar moieties can enter to form inclusion complex. Complex formation between cyclodextrin and a substrate is assessed by its binding/stability constant.

Yvaraja et al, in 2014[10] prepared solid dispersion of carvedilol for enhancement of aqueous solubility. To increase solubility polymers like Beta Cyclodextrin, Hydroxypropyl-beta-cyclodextrin were used. The following solid dispersion were then evaluated through phase solubility studies, determination of partition coefficient, drug content (%) and in vitro dissolution studies.

Domanska et al, in 2011, investigated[11] the guest host complex formation of three drug derivatives of anthranilic acid, mefenamic acid, niflumic acid with 2-hydroxypropyl-β-cyclodextrin in aqueous solutions. It was found that solubility of sparingly soluble drugs has been improved by the addition of 2-hydroxypropyl-β-cyclodextrin at two temperatures 298.15 K and 310.15 K and two pH values 2 and 7.

The Biopharmaceutics classification system:

It is a system to differentiate drugs on the basis of their solubility and permeability. It is a guide for predicting the intestinal drug absorption provided by the U.S Food and Drug Administration.

According to the Biopharmaceutics Classification System, drug substances are classified as follows:

1. Class I-high permeability, high solubility: Those compounds are well absorbed and their absorption rate is usually higher than excretion.
2. Class II-high permeability, low solubility: The bioavailability of those products is limited by their solvation rate.
3. Class III-low permeability, high solubility: The absorption is limited by the permeation rate but the drug is solvated very fast. If the formulation does not change the permeability or gastrointestinal duration time, then Class I criteria can be applied.
4. Class l-high permeability, high solubility: Those compounds have a poor bioavailability. Usually they are not well absorbed over the intestinal mucosa and a high variability is expected.

MATERIALS AND METHODS USED:

Polymers used:

1. Hydroxypropyl-β-cyclodextrin (HPβCD), (Tokyo Chemical Industries Co. Ltd)
2. Polyvinyl pyrrolidone (PVP K-30), (Loba Chemie, Mumbai)

Drug used:

Metaclopramide HCl (Yarrow Chemical)

Reagents used:

Potassium dihydrogen phosphate (Merck Specialities Pvt Ltd.), Sodium hydroxide (Merck Specialities Pvt Ltd.), sodium chloride (Qualichems Pvt Ltd New Delhi)

Solvents used: acetone (Quest Chemicals, Kolkata), methanol (Spectrochem Pvt Ltd. Mumbai), ethanol (obtained from departmental store of Pharm Tech. Jadavpur University), Double distilled water (obtained from lab of Pharmaceutical Engineering, Pharm Tech dept. Jadavpur Univ.)

Instruments: UV Visible Spectrophotometer (ANALAB, UV 180), Water bath (Integrated electrolyte system by SUNBIM), Magnetic stirrer (Trasons, multispins)

Conversion of Metaclopramide hydrochloride to Metoclopramide base form:

Metoclopramide base form is required which is usually available in its hydrochloride form. Required amount of Metoclopramide hydrochloride was dispersed in sufficient double distilled water followed by stirring until the total amount of drug gets fully dissolved. The solution was neutralized by 1 M sodium hydroxide solution and gradually a precipitate was formed. The precipitate was collected by filtration and the precipitate thus obtained was washed several times with double distilled water to remove HCl which was produced during precipitation. The wet precipitate was dried in hot air oven at 50 degrees Celsius. Afterwards the solid material was cooled up to room temperature (25 degrees Celsius). Next, dried solid material
was treated with acetone to make a saturated solution ad stirred continuously at 50 degree Celsius. The solution was allowed to attain room temperature and thereafter it was kept in a refrigerator and crystal particles of Metaclopramide (base form) were formed and collected and dried in 50 degrees Celsius in hot air oven. The material was cooled at room temperature and it was weighed.

**Determination of aqueous solubility of drug:**
Aqueous solubility study was performed by taking excess amount of Metaclopramide in an aqueous phase (phosphate buffer pH 7.4, double distilled water, phosphate buffer pH 6.8 and pH 5.5 buffer) and shaken at 37°C, 40°C, 45°C. After 24 hours absorbance was observed to obtain solubility.

**Phase solubility study:**
Phase solubility was carried out by dissolving known amount of polymers with increasing amount to each of series of test tubes containing aqueous phase (phosphate buffer pH 7.4, double distilled water). Thereafter excess amount of drug was added to each of the tube and shaken for 24 hour at 25°C, 37°C, 40°C, 45°C respectively. After 24 hour, very slight quantity of insoluble material (drug) was observed at the bottom of each test tube and then content of each test tube was filtered and filtrate was collected and its absorbance recorded. Phase solubility curve was constructed and thermodynamic and binding constants were calculated.

**Preparation of Metaclopramide Solid dispersion:**
Solvent evaporation technique was carried out by dispersing physical mixture and polymer at certain common ratio and then it was evaporated until transparent solvent free thin layer of mass was obtained. Then the film was dried till constant weight at 50 degrees Celsius.

**RESULTS AND DISCUSSION:**
λ<sub>max</sub> of Metaclopramide base determined first by scanning solution of Metaclopramide in UV Spectrophotometer. λ<sub>max</sub> was found to be 272 nm.

Preparation of calibration curve: The standard curves was prepared by plotting absorbance against concentration of individual analysts.

The calibration graph was found linear in range of 2 to 12 g/mL in Double distilled water; pH 5.5

The phase solubility study is carried out to determine binding/complexation of polymer-drug complexes. These complexes effectively modify solubility characteristics of drug. Phase solubility studies of binary systems (MET-HPβCD, MET-PVP K-30) were performed to see effects of complexation ability of different carrier systems. The shapes of phase solubility profiles were found to be A<sub>I</sub> type isotherms for PVP K-30 and HPβCD. A<sub>I</sub> type linear profile suggests solubility enhancement of a guest molecule as a function of carrier’s concentration. The profiles showed different values of intercept and slope as temperature and pH of media were varied. Stability constant was calculated by intercept and slope of linear part of profile. The apparent complexation constants (K<sub>c</sub>) and thermodynamic parameters (ΔG<sub>ΔH</sub>, ΔS) of the phase solubility studies with three aqueous media (DDW, pH 5.5) at different temperatures (298 K, 310 K, 313 K, 318 K).

Free energy change for these binary combinations was found negative which indicate spontaneous solubilization. Free energy changes varies from -9 to -11 kJ/mol. It suggests that drug may bind with the carrier molecules which are held by weak physical forces like Vander waals forces, hydrogen bonding and some hydrophobic forces.

Effect of temperature on k in pH 5.5 was much prominent in each binding in comparison with that of DDW. With the rise of temperature mobility of ionic species of MET in acidic pH increases which in turn possibly inhibits complex formation with the carriers. Complexation is of exothermic type, entropy changes were found negative in pH 5.5. Higher K values for MET-PVP K-30 system was observed in comparison with that of MET-HPβCD. MET-PVP K-30 showed low solubility because of influence of high stability constant. If stability constant is too high it may form a more stable complex so drug may not be released out to a greater extent from complexed state.

![Graph showing solubility in DDW with HPβCD carrier](image)

Fig 5: Effect of carrier (HPβCD) drug ratio of solid dispersion on solubility of MET in DDW
In the following tables saturation solubility of solid dispersions of Metoclopramide prepared with various carriers was shown. Metoclopramide is sparingly soluble in double distilled water (DDW). Its aqueous solubility in double distilled water increases linearly keeping drug amount fixed when fraction of carrier substance in solid dispersion of drug is increased. As drug amount was fixed (100 mg) its solubility was enhanced up to 5:1 and drug amount was not much higher on further increase of HPβCD. Enhancement of solubility was observed in binary system of carrier drug (3:1) in DDW, approximately 2-3 times.

Solubility in acidic pH of 5.5 was higher than DDW and it was observed that solubility of drug in pH 5.5 is 28.95 times higher than that of pure drug in DDW samples without any carrier substances.

In case of solid dispersion of PVP K-30, drug solubility enhancement was lesser in comparison with that of HPβCD. Its solubility increases linearly with the increase of amount of carrier in solid dispersion.

CONCLUSION:
Poor solubility of new chemical entities is a well known problem for the past few decades. Several formulation strategies have been proposed to overcome this. Despite the imbalance between significant research efforts and the few successful marketed formulations the solid dispersion technology still holds a key position among the various formulation strategies to enhance the aqueous solubility/dissolution rate and thereby oral bioavailability of poorly soluble compounds. But only few solid dispersion products are available in market because many others have stability problems. The various processing parameters are involved in the preparation of solid dispersion which influence the effectiveness, usefulness, stability, and safety of the formulation. The use of systemic experimental design along with mathematical optimization is both time and cost efficient and its application assures the formulation quality.

The main objective was to develop modified release dosage form of poorly soluble drugs in an attempt to improve oral bioavailability20,21.
