INTRODUCTION:

The careful review of physiological literature for bryophytes presented in the last few decades devote very little attention to their chemical properties. Moss biochemistry is not completely unknown, however, since their lipid-soluble pigments, and their proteinaceous compounds have been investigated in considerable detail and found to be essentially similar to such compounds found in other groups of green plants. Flavonoids are produced in Marchantiales, along with glycoside uronic acids and minor amounts of apigenin and luteolin glycosides in Marchantiales. It is suggested that flavonoids are widely distributed within the mosses and that many of these flavonoids may be rare and unusual types which have a narrow systematic distribution. Flavonoids are produced in part from the same intermediates which polymerize to form lignin. In order for a plant to accumulate such compounds it must be able to synthesize C6-C3 Phenylpropanoid compounds such as phenolic acids, demonstrated that some bryophytes possessed the ability of carrying out phenol glycosylation reactions. Thus the phenolic chemistry of the bryophytes was found to be worth studying in detail.

Mosses also seem to have potential for studies in biochemical systematic, since they also produce pigments such as chlorophyll and anthocyanins.

Studies were thus undertaken to elucidate the moss biochemistry with respect to pigments and phenolics.

MATERIALS AND METHODS:

Riccia, Plagiochasma and Targionia was collected from Purander Fort near Saswad. All these forms are included in order Marchantiales. Care was taken to insure that the collection was composed of only one species that no extraneous plant material was included. Liver-works are comparatively small plants. The plant body is dorsiventral gametophyte, independent, either thallose foliose, or all the specimens collected were washed with water to remove soil particles. The gametophytic stages of all the three specimens were collected.

Riccia: Plants Small, Greyish, dichotomous, overlapping patches. Dorsal groove deep and narrow at the apex or slightly concave towards posterior side. Scales prominent. Overlapping deep purple. Rhizoids smooth and tuberculated. Fig. 1.

Three genera viz. Riccia, Plagiochasma and Targionia were studied biochemically. It was found that amount of total chlorophylls and polyphenol content is more in Targionia as compared to Riccia and Plagiochasma Flavonoids are also studied adopting chromatography technique and when the spots viewed under UV were found to be of similar type in Riccia and Plagiochasma, whereas Targionia showed the present of only one spot identical to the second spot isolated in Riccia, and Plagiochasma.

Keywords: Biochemical, Riccia, Plagiochasma, Targionia, pigments, phenolics.
**Plagiochasma**: Plants are pale-green in colour, ribbon-shaped, flat. Thallus apex is forked. Margins purple from ventral side undulate. Rhizoids are simple, male receptacle horse-shoe shaped. Fig. 2

**Targonia**: Plants thallose, terrestrial, prostrate, thallus is simple, with innovations ventrally present near the apex. With distinct areoles on the dorsal surface. Sporophyte is simple, with innovations ventrally present near the apex. Targionia: Plants thallose, terrestrial, prostrate, thallus is

**METHODS:**

1. Total Polyphenol estimation by Folin method of Swan and Hills
2. Total chlorophyll estimation by Arnon method.
3. Flavonoids

**1. Total polyphenol estimation:**

Total polyphenol was estimated by the Folin method of 

One gram of the material was stirred for 30 minutes with 8 ml aliquots of 80% v/v ethanol over a period of 35 minutes using a glass homogenizer. The successive extracts were combined and made up to 25 ml. A suitable aliquot, say 1 ml of the ethanolic extract was diluted with distilled water to about 8 ml; then 0.5 ml of Folin-phenol reagent was added and the contents were well mixed. After 3 minutes, 1 ml of saturated sodium bicarbonate solution was added and the final volume was made up to 10 ml with distilled water. The tubes were thoroughly shaken and the colour development was measured at 725 nm after standing for 60 minutes. A standard curve was prepared using standard tannic acid and all the concentrations were expressed in terms of micrograms of this compound.

**2. Total Chlorophyll estimation:**

The total chlorophylls were estimated by the method given by 

One gm. of the leaves was crushed in a mixture of 80% acetone (v/v) with NH4 OH (4 ml/L) and a pinch of MgCO3. The homogenate was filtered through Buchner funnel. The filtrate was made to a volume of 10 ml by adding 80% acetone. The absorbance of this filtrate was recorded at 663 and 645 nm on spectronic 20 colorimeter.

**3. Flavonoids**

A small amount of plant tissue was immersed in 2 M HCL and heated in a test tube for 30-40 min at 100°C. The cooled extract was then filtered and extracted with ethyl acetate since the solution was coloured (either because the original) tissue was coloured with anthocyanin or because colour was formed from anthocyanidin during acid treatment. The aqueous extract is further heated to remove the last traces of ethyl acetate and re extracted with a small volume of amyl alcohol. The ethyl acetate is concentrated to dryness, taken up in 1-2 drops of ethanol and aliquots chromatographed one dimensionally on a paper Chromatogram using, Forestal solvent system (acetic acid alcohol-water) 30:3:10. The spots obtained were observed under ultra violet light.

**RESULTS AND DISCUSSION:**

**Table 1**: Polyphenol content in mg/gm fresh wt of material ± Std. error.

From the above results it is clear that the amount of total polyphenols is more in *Targionia* as compared to *Riccia* and *Plagiochasma* (Table 1).

It is also obvious from Table-2 that the amount of Pigments Chlorophyll: a. Chlorophyll: b and total chlorophylls are more in *Targionia* with respect *Riccia* and *Plagiochasma*. Chloroplasts have been postulated to play a special role in the synthesis of phenolic compounds either in the stroma or tightly associated with thylakoid membranes. An interesting feature of bryophyte is that they are relatively free from attack by parasitic microorganisms. Herbarium specimens of these plants need no special treatment like those of higher plants.

The cause of this may be anatomical, immunological or may be due to the presence of antimicrobial activity of some factors. There is a need for more information on these points. The number of compounds, with limited information on their chromatographic characteristics is presented in Table-3. Flavonoid has been detected in all the three genera studied. The chromatograms when exposed to UV light showed that *Riccia* and *Plagiochasma* possessed the same types of flavonoids (Table-3) whereas *Targionia* showed the presence of just one flavonoid. Flavonoids are produced in part from the same intermediates which polymerize to form lignin.

It has been recognized for many years that mosses can produce compounds to strengthen in the cell walls as does the lignins. The precise type of flavonoid obtained in our results needs further investigations. In addition to their unusual presence, there is evidence that their intracellular localization may also be unusual. It is suggested that flavonoid are widely distributed within the mosses and many of these may be rare and of unusual type which have a narrow systematic distribution.
