Abstract

Introduction: Diospyros mespiliformis Hochst. ex A. Rich (Ebenaceae) is a nutritional, artisanal and medicinal plant. It is used in alternative medicine in Burkina Faso for the treatment of conjunctivitis, menorrhagia, dysentery, and especially diarrhea. Aims: Our study aimed to evaluate the chemical profile, the antioxidant and anti-inflammatory activities, the safety of use, and the spasmodic effects of the fractions obtained from the aqueous decoction of the leaves of Diospyros mespiliformis. Methods: Phytochemical screening by HPTLC and the determination of compounds of interest were carried out. The antioxidant activity was evaluated according to the ABTS, DPPH, FRAP, and LPO methods. The inhibitory activity of Pharmolipin A2 and 15-lipoxigenase was evaluated. Acute oral toxicity was carried out on female mice (NMRI). The ex vivo spasmodic effect of the fractions was tested on isolated rat duodenum using ACh and BaCl2 as contracting agents. Results: At the end of these tests, the fractions contain flavonoids, tannins, steroids, triterpenes, and saponosides. The content of total phenolics was respectively for the ethyl acetate fraction (EAF) and the residual aqueous fraction (RAF) 84.15±1.73 mg EAT/g and 89.67±2.35 mg EAT/g. That of flavonoids was respectively 45.91 ± 0.98 mol EAA/g and 43.80 ± 6.31% for LPO, respectively, and an inhibition % of 43.80 ± 6.31% for LPO. For RAF, the IC50 were in the same range as EAF of 16.92±0.23 μg/mL, 18.58±2.91 μg/mL, 1138.4±1 mol EAA/g and an inhibition of 45.14±0.35% for LPO. The fractions had an inhibitory effect on phospholipase A2 compared to Betamethasone. Finally, the most active EAF caused a spasmodic effect with Emax of 87.4±15.71% and 90.4±7.84%, respectively, during contractions induced by BaCl2 and ACh. Conclusion: Finally, this work provided scientific data and could justify the use of Diospyros mespiliformis leaves in the treatment of diarrhea.

Keywords: Diospyros mespiliformis, Leaves, Antioxidants, Anti-inflammatory, Safety of use, Spasmylytic

INTRODUCTION

In alternative medicine, plants are a source of bioactive compounds. In fact, 80% of the population in developing countries rely on these bioactive compounds for their healthcare. Gastrointestinal diseases also figure prominently among the population's various ailments. In 2019, there were 8 million deaths from digestive diseases, and this figure is not in decline over three decades. The spasmylytic effect of drugs is commonly used to reduce excessive contractility of the intestine, responsible for cramps and discomfort in the abdominal region. Several strategies are used in this treatment, both in modern and traditional medicine, using medicinal plants. In scientific terms, ethnobotanical, biochemical, pharmacological, and toxicological studies and clinical trials have been conducted to provide evidence of the use of plant drugs. To this end, among the plant species widely used for their medicinal properties is Diospyros mespiliformis Hochst. ex A. DC (Ebenaceae). Studies carried out on this plant have demonstrated the anti-proliferative properties of trunk bark extracts and the antioxidant and antimicrobial activities of organic leaf extracts.
plasmoidal activity of Diospyros mespiliformis trunk bark and leaf extracts on Plasmodium berghei has also been demonstrated \(^6\). The inhibition of the \(\alpha\)-glucosidase enzyme by bioactive compounds isolated from Diospyros mespiliformis has been documented \(^10\). Preliminary studies have shown that the aqueous decoction of the plant’s leaves has spasmyloytic effects. However, the antispasmodic properties of leaf fractions have not yet been elucidated. It was therefore essential to assess the safety and spasmyloytic efficacy of the ethyl acetate and aqueous residual fractions of Diospyros mespiliformis leaves.

**MATERIAL AND METHODS**

**Chemicals and Reagents**

Chloroform, Ethyl acetate. Methanol, formic acid, Hexane, Dimethyl sulfoxide (DMSO), NEU reagent, aluminum trichloride, iron chloride, foline chlorotetrazo reagent (FCR), sulphuric anhydride reagent, Liebermann and Burchard reagent, monobasic potassium phosphate, sodium phosphate dibasic, 15-lipoxygenase (EC 1.13.11.12), linoleic acid, sodium bicarbonate, potassium hexacyanoferrate, trichloroacetic acid (TCA), thioctic acid (TBA), hydrogen peroxide solution, 2,2'-azinobis-[3-ethylbenzothiazoline-6-sulfonyl] (ABTS), 2,2-diphenyl-1-picrylhydrazyl (DPPH), and potassium persulfate were purchased from Sigma-Aldrich (St. Louis, MO, USA). Gallic acid, Quercetin, Ascorbic acid, Trolox, Betamethasone, and Zileuton were supplied by Sigma Aldrich. Silica gel TLC plates F 254 grade was from Macherey-Nagel (Germany).

**Plant material**

Fresh leaves of Diospyros mespiliformis Hochst. ex A. DC (Ebenaceae) were collected in May 2022 in Goundi, in the Sanguié Province of Burkina Faso. A botanist from the Laboratoire de biologie végétale et d’écologie de l’Université Joseph Ki-Zerbo, Burkina Faso, identified and authenticated a sample. A specimen exists under number 4267 (OUA).

**Preparation of the leaves fractions**

Leaves fractions were prepared by making an aqueous Diospyros mespiliformis leaves powder decoction. One hundred (100) g of the plant powder was dissolved in 500 mL of distilled water and boiled for 30 min. After cooling, the supernatant was filtered through a fine mesh nylon cloth and centrifuged at 2000 rpm for 5 min to give the aqueous decoctate. The decoctate was subjected to liquid-liquid fractionation with ethyl acetate. This organic phase was concentrated in a rotavapor at 70 °C and oven-dried at 60 °C to give the ethyl acetate fraction, EAF (0.85%). The residual aqueous phase was freeze-dried to give the residual aqueous fraction, RAF (11.33%). These 2 fractions were used for the various tests.

**Phytochemical Investigation: High-performance thin-layer chromatography**

High-performance thin-layer chromatography (HPTLC) was used to detect flavonoids and tannins in the two fractions (EAF and RAF). It was carried out on chromatoplates (60 F254, 10 x 5 cm, glass support 10 x 20 cm, Merck) following the literature \(^11\). Approximately 20 μL of each extract was streaked with a semi-automatic sample dispenser (CAMAG, Linomat 5, Switzerland) along the baseline 0.8 cm from the bottom edge of the plate. After deposition and drying, the plates were placed in a tank containing eluent previously saturated (2 x 1 dm, saturation time: 30 min). The solvent system used depended on the metabolite to be identified: ethyl acetate/formic acid/H₂O, (8/2/1 v/v/v/v) for flavonoids; ethyl acetate/formic acid/H₂O (18/2/4/2/1 v/v/v/v/v) for tannins; ethyl acetate/hexane (8/2 v/v) for sterol-triterpenes and hexane/ethyl acetate/methanol (10/5/5 v/v/v) for saponosides. After migration over 8 cm in length, the plates were dried, and NEU reagent for flavonoids, sulphuric anisaldehyde reagent for saponosides, Liebermann and Burchard reagent for Sterol-triterpenes and 5% FeCl₃ for tannins revealed the chromatographic profiles. The profiles were then observed under visible light (tannins) and at UV wavelengths of 366 nm.

**Determination of flavonoid compound**

Flavonoid content was assessed using an Aluminium chloride reagent \(^12\). A standard calibration curve was plotted with Quercetin. One hundred (100) μL of EAF or RAF (1 mg/mL) were mixed with 100 μL of a 2% w/v Aluminium trichloride solution. After 10 min, absorbance was measured using a mass spectrophotometer. Absorbance at 415 nm was measured using a spectrophotometer (Epoch Biotek, USA) after 10 min. Results were expressed as mg Quercetin equivalent (QE)/g dry extract.

**Assessment of antioxidant properties**

**DPPH**-**E**say

Free radical scavenging activity of EAF, RAF, and Trolox was performed using 2,2-diphenyl-1-picrylhydrazyl (DPPH) as previously described \(^13\). The absorbance of 10 μL of samples and Trolox added to 200 μL of DPPH (0.04 μg/mL) was measured at 490 nm after 30 min of incubation in the dark at room temperature using a Bio-Rad spectrophotometer (model 680, Japan). The result was expressed as antioxidant capacity equivalent to Trolox. As a function of sample concentration, a DPPH inhibition percentage curve was plotted. The percentage inhibition of the DPPH radical was calculated using the following formula:

\[
\text{Inhibition} \% = \left[\frac{(A_0 - A_f)}{A_0}\right] \times 100
\]

where \(A_0\) and \(A_f\) represent the absorbances of the extract/ascorbic acid and the control (DPPH solution without sample). The concentration required to inhibit 50% of DPPH (IC₅₀) was determined on the curve.

**Ferric Reducing Antioxidant Power (FRAP) Assay**

The FRAP assay was performed on EAF, RAF, and Trolox as previously described \(^14\). The mixture of 0.5 mL samples with 1.25 mL phosphate buffer and 1.25 mL potassium hexacyanoferrate aqueous solution (1%) was incubated for 30 min at 50 °C. Next, 1.25 mL of trichloroacetic acid (10%) was added and centrifuged at 3000 g for 10 min. FeCl₃ solution (0.125 mL, 0.1%), and distilled water (0.625 mL) were added to the supernatant (0.625 mL). The absorbance of the reaction medium was measured at 700 nm using a spectrophotometer (Agilent, Santa Clara, CA) equipped with ChemStation UV-visible software. Trolox was used to plot the calibration curve. The FRAP activity of EAF and RAF was expressed as μmol Trolox equivalent/gram dry extract.

**ABTS**-**E**say

The ABTS free radical scavenging activity of EAF, RAF and Trolox was assessed using the procedure described previously \(^12\). In a volume of 5 mL of distilled water, 19.2 mg of ABTS were dissolved. Potassium persulphate (3.312 mg) was added to the ABTS solution (3.84 mg/mL). After adding the potassium persulphate, the solution was kept for 16 h in the dark at room temperature before use. On the day of the experiment, 4.5 mL of the mixture was diluted in 220 mL of absolute ethanol. The range of 8 dilutions to be tested was prepared from the parent concentration of the samples (1 mg/mL). On a 96-well microplate, 200 μL of ABTS solution mixed with 20 μL of EAF or
RAF or Trolox were added to each well. After incubation for 30 min at 25°C, absorbances were read against a blank at 415 nm using an Agilent 8453 spectrophotometer with ChemStation UV-visible software. Measurements were performed in triplicate. The percentage inhibition was calculated according to the formula:

\[ \% \text{Inhibition} = \left( \frac{A_0 - A_i}{A_0} \right) \times 100 \]

A0 is the absorbance of the control; Ai is the absorbance of the sample.

The absorbance inhibition curve as a function of the concentration of the extract or reference substance (Trolox) was constructed to determine the 50% inhibitory concentration (IC50). Anti-radical power (ARP) was determined using the formula: \[ \text{ARP} = \frac{C}{A} \]

The absorbance inhibition test as a function of the concentration of the extract or reference substance (Trolox) was performed in triplicate and the percentage inhibition of absorbance at 415 nm was calculated according to the formula:

\[ \% \text{Inhibition} = \left( \frac{AE - AI}{AE} \right) \times 100 \]

**Lipid Peroxidation Inhibition (LPO) Assay**

The lipid peroxidation activity of rat liver was determined according to the method of Najafpour et al.12, FeCl₂·H₂O was used to induce peroxidation of liver homogenate. A 0.2 mL volume of EAF or RAF (1.5 mg/mL) was mixed with 1 mL of 1% rat liver homogenate, then 50 μL FeCl₂ (0.5 mM) and 50 μL H₂O₂ (0.5 mM) were added. The mixture was incubated for 60 min at 37°C, then 1 mL trichloroacetic acid (15%) and 1 mL 2-thiobarbituric acid (0.67%) were added. The mixture was heated in boiling water for 15 min. The experiment was performed in triplicate and the absorbance was read at 532 nm. Trolox was used as the reference product. The percentage inhibition was calculated as the following formula: Percentage inhibition (%) = [1-(A0 - Ai)/A0] x 100

A0 is the absorbance of the control (without sample); Ai is the absorbance with the sample; A0 is the absorbance without liver homogenate.

**Anti-Inflammatory Activity**

**Phospholipase A2 (sPLA2) Inhibition Assay**

The sPLA2 activity of bee venom was determined according to the method of the manufacturer Abcam (Japan) described in catalog no. ab133089. A 96-well microplate was used to perform the sPLA2 inhibition assay. A final concentration of 100 μg/mL of EAF, RAF and Betamethasone (reference compound) was used. Absorbances were read spectrophotometrically (Agilent 8453) at 415 nm against a blank that had not received the enzyme. The experiment was performed in triplicate and the percentage inhibition of sPLA2 at 100 μg/mL was calculated using the following formula: Inhibition (%) = [(AE - AI)/AE] x 100

**Lipoxygenase Inhibition Assay**

Lipoxygenase inhibition was determined using linoleic acid (1.25 mM) as substrate.12 Inhibitors (EAF or RAF / reference substance: Zileuton) were prepared to a final concentration of 100 μg/mL. 146.25 μL of 15-lipoxygenase solution (820.51 U/mL) was added to 3.75 μL of each inhibitor. Next, 150 μL of linoleic acid was added. A spectrophotometer (Epoch Biotek Instruments, USA) was used to measure absorbances at 234 nm against enzyme-free blanks. The tests were carried out in triplicate and the percentage of lipoxygenase inhibition was calculated using the formula:

Inhibition (%) = [(AE - AI)/AE] x 100

AE: Absorbance enzyme test - Absorbance blank; AI: Absorbance inhibition test - Absorbance blank.

**Experimental animals**

Female NMRI (Naval Medicinal Research Institute) mice and Wistar male rats with average weights of 27 ± 4 g and 185 ± 23 g, respectively from the animal house of the "Institut de Recherche en Sciences de la Santé/Centre National de Recherche Scientifique et Technologique (IRSS/CNRST), Burkina Faso" were used. The animals were placed in an enclosure at a temperature of 21-23°C with a relative humidity of 55 ± 5% and subjected to the light/dark cycle of 12 h/12 h according to the rearing conditions of these species. Standard laboratory pellets enriched with proteins (29%) and water were provided for satiation and experiments were carried out following the procedures of the Guide of Good Practices in Animal Experimentation under the Declaration of Helsinki. Furthermore, all experimental animal procedures have been performed by the Guide for the Care and Use of Laboratory Animals of the US National Institutes of Health and the EU Directive 2010/63/EU for animal experiments.12, 13.

**Acute Oral Toxicity**

The acute oral toxicity test for EAF and RAF was performed on female NMRI (Naval Medicinal Research Institute) mice in accordance with OECD guideline 423.15 Two batches, each consisting of three mice, were made up and placed separately in polypolyethylene cages, a control batch of 03 mice and a test batch of 03 mice. EAF and RAF was administered by gavage using an esophageal tube in a single dose to the test mice after fasting for 3 h. A dose of 2000 mg/kg body weight of EAF and RAF was chosen as the starting dose. Control batch received the solvent for dissolving the extract (distilled water, 10 mL/kg). The mice were observed individually for 2 h after administration, at the end of which food was restored. They were then observed twice daily for a period of 14 days to monitor for mortality and signs of toxicity such as hair standing up, excitement, vomiting, hyperventilation, diarrhea, lack of appetite, sleepiness. The weight of each mouse and the quantities of water and food consumed were measured every 2 days during 14 days of experimentation. On day 15, the mice were sacrificed and a necropsy was performed on the organs (liver, kidneys, lungs, spleen, and heart) then weighed. The relative weight of each organ was calculated [(Organ weight (g) / Fasting mouse weight on the day of sacrifice (g)) x 100]. This test was repeated after the mice were sacrificed under the same conditions as the 2 other batches (control batch and extract batch).

**Spasmyloytic effect of two fractions on isolated rat duodenum**

The protocol used has been described by Boly et al.14. Wistar rat is fasted for 24 h before the start of the experiment and then sacrificed. A portion of the duodenum is removed and the isolated organ bath thermostated at 37°C, with a pneumatic bubbler for organ oxygenation. One end of the isolated intestine fragment is attached to the hook of the support rod, and the other end to the isometric transducer, which in turn is connected to the recorder via an amplifier. This device visualizes the contractions of the isolated rat duodenum. The Tyrode solution is renewed every 15 min during the 45 min stabilization period. After observing the regularity of the contractile activity of the isolated organ, KCl (80 mM) is administered into the vessel to stimulate the organ, followed by rinsing. Solutions of the fractions (EAF and RAF) are administered on the one hand, and on the other, after precontraction with acetylcholine (AChL 10⁻⁶ M) or barium chloride (BaCl₂ 160 μg/mL). This makes it possible to assess, respectively, the extract’s effect on normal contractile activity.
in the isolated intestine and its interaction with the cholinergic system and potassium fluxes in the cells. The percentage inhibition of contraction (PI) is calculated using the following formula:

$$PI = \left( \frac{h_1 - h_2}{h_1} \right) \times 100$$

h1: height of peaks due to contractor alone; h2: height of peaks due to contractor in the presence of extract.

**RESULTS**

**HPTLC phytochemical investigation**

The phytochemical analysis of EAF and RAF highlighted the presence of saponosides, tannins, flavonoids, and sterol-triterpenes (Figure 1).

![Phytochemical profile of ethyl acetate fraction (EAF), and residual aqueous fraction (RAF) revealed by HPTLC](image)

**Total phenolic and flavonoid contents in *D. mespiliformis* fractions**

QE: quercetin equivalent; TAE: tannic acid equivalent; ***p < 0.001 vs EAF

The total phenolic and flavonoid contents are shown in Table I. These results are expressed in milligrams of tannic acid equivalent per gram of dry extract for total phenolics (mg TAE/g) and in milligrams of quercetin equivalent per gram of dry extract (mg QE/g) for flavonoids. The two fractions showed the similar value of Total phenolic compound content and Ethyl acetate fraction had a high flavonoid compound content.

**Biological activities**

**Antioxidant activity**

The antioxidant activity of *Diospyros mespiliformis* leaves fractions is shown in Table II. EAF had an IC50 of 2.26±0.16 µg/mL using the ABTS test. This was statistically significant compared to Trolox (3.78±0.21 µg/mL). For the DPPH radical reduction method, the IC50 were 22.34±7.23 µg/mL and 18.58±2.91 µg/mL respectively for EAF and RAF. Significance was obtained between the IC50 of these two fractions and the reference compound (Trolox, 6.34±0.04 µg/mL). The ferric ion reduction capacity (FRAP) was 1136.25±0.90 mol EAA/g (EAF) and 1138.4±1.27 mol EAA/g (RAF). The lipid peroxidation inhibitory power (LPO), expressed as a percentage (%) (at 100 µg/mL) was 43.80±6.31% for the EAF, 45.14±10.35% for RAF and 48.11±3.88% for Trolox.

**In Vitro Anti-inflammatory activity**

The evaluation of the *in vitro* anti-inflammatory activity of the two leaves fractions by inhibiting 15-lipoxygenase and Phospholipase A2 is recorded in Table III. EAF, and RAF have similar effects in terms of inhibition on 15-lipoxygenase. However, the Zileuton presented a better IC50, 2.92±0.32 µg/mL (**p < 0.001**). The evaluation of the effect of fractions on the activity of Phospholipase A2 expressed as a percentage of inhibition shows that there was no statistical difference between EAF, RAF, and Betamethasone (reference substance).

**Changes in body weight, food, and water consumption of mice after 14 days of monitoring**

Figure 2 shows the mean weight gain, feed consumption (g/g of mice), and water consumption (mL/g of mice) for 14 days in female mice given a vehicle (1% Tween 80, 10 mL/kg), a single dose (2000 mg/kg) of RAF, and 300 mg/kg of EAF. There was no statistically significant difference in body weight gain between the treated and control batches.
Macroscopic observation and relative organ weights of mice

Fresh macroscopic examination of vital organs such as the heart, lungs, liver, kidneys, and spleen of control mice and mice treated with EAF and RAF showed that there were no lesions, nor any change in color or appearance of the various organs. Table V shows the relative organ weights of batches of control mice and mice treated with EAF (300 mg/kg) or RAF (2000 mg/kg). No statistically significant variation was observed between the relative organ weights of control and treated batches.

Table V: Relative weights of female mice from control and test batches with *D. mespiliformis* leaves fractions during 14 days of follow-up; *n* = 6

EAF: Ethyl acetate fraction; RAF: Residual aqueous fraction

Antispasmodic effect of EAF and RAF of *D. mespiliformis* leaves on isolated rat duodenum

The results of the relaxation of the isolated rat duodenum the two fractions (EAF and RAF) of *D. mespiliformis* leaves and vehicle are presented in Figure 3. Figure 3A shows the relaxation curves for both fractions and the control on the isolated duodenum precontracted with ACh. The EAF curve was more deviated to the left compared to RAF and control. The histogram (figure 3B) shows the Emax of EAF (90.40±7.84%), RAF (40.21±12.79%) and control (0.88±0.42%). A statistically significant difference was noted between the effects of the two fractions compared with the control. Figure 4A shows similar relaxation results obtained with the fractions and the vehicle (control) on the isolated rat duodenum pre-contracted with BaCl2. With a statistically significant difference, Figure 4B presented the Emax of the EAF (87.4±15.71%) and RAF (51.81±12.88%) fractions and the control (10.91±7.48%).
DISCUSSION

Traditional herbal medicine has been used to treat illnesses since ancient times. This practice is used to treat gastrointestinal disorders. As such, the leaves of Diospyros mespiliformis are widely used as an antispasmodic. The aim of this study was to provide scientific data on the use of the plant in the treatment of diarrhoea in alternative medicine. The phytochemical screening of Diospyros mespiliformis leaves fractions is comparable to that reported in studies showing that D. mespiliformis leaves contain flavonoids, tannins, sterols, terpenes and saponosides. These phytochemicals neutralise reactive oxygen species and superoxides, while other flavonoids can trap the highly reactive oxygen radical known as peroxynitrite. Flavonoids have anti-inflammatory and antispasmodic properties. They also have anti-inflammatory, anti-diarrhoeal, anti-parasitic and antibacterial properties. In addition, total phenolic content was measured in the ethyl acetate fraction (84.15±1.73 mg TAE/g) and the residual aqueous fraction (89.67±2.35 mg TAE/g). Higher levels of total phenolic compounds in aqueous, ethanolic, methanolic and petroleum ether extracts of Diospyros mespiliformis leaves have been demonstrated. These compounds are known for their spasmolytic properties. In addition, phenolic compounds, in particular flavonoids, tannins and triterpenes, are inhibitors of certain pro-inflammatory enzymes, chelators of heavy metals involved in the production of free radicals and the regulation or protection of the antioxidant defence system. The antioxidant properties of D. mespiliformis leaves extracts have already been demonstrated. Moreover, the spasmolytic mechanism, inflammation of the viscera cannot be ignored, hence the search for anti-inflammatory properties in the fractions. Overall, the fractions showed good inhibition of phospholipase A2 and 15-lipoxigenase. These anti-inflammatory activities were less effective than Zileuton, but similar to Betamethasone. These results confirm the anti-inflammatory properties of the plant’s leaf fractions. The flavonoids and sterols/triterpenes in the fractions are known for their ability to inhibit pro-inflammatory enzymes. In addition, for the safe use of both fractions, acute oral toxicity was assessed. The results showed that acute oral administration of the EAF fraction (2000 mg/kg bw) resulted in mortality in mice. This finding indicates that EAF should be used sparingly. However, EAF (300 mg/kg bw) and RAF (2000 mg/kg bw) did not cause any mortality or behavioural changes. Thus, the LD₅₀ of these two fractions was estimated at 1000 mg/kg and 5000 mg/kg bw respectively for EAF and RAF according to the United Nations Globally Harmonised System. These results suggest that at very high doses, AEF can have harmful effects on consumers. In line with the literature, work has shown that the methanolic extract of the leaves and bark of the trunk of Diospyros mespiliformis, as well as their hexane, ethyl acetate and butanol fractions, can be safely consumed. Pharmacological results showed that EAF and RAF have muscle relaxant properties on isolated rat duodenum after stimulation of acetylcholine receptors by ACh with best efficacy for RAF. EAF induces a significant positive tonotropic effect marked by a contractile and plateau contractile activity reflecting the increased peristalsis of the gastrointestinal tract. ACh induces contraction through the activation of G protein-coupled smooth muscle M₅ receptors, leading via Inositol Triphosphate (IP₃) to the release of intracellular Ca²⁺. This curative experiment shows that EAF and RAF have anticholinergic properties. This property can be explained by the presence of tannins, flavonoids, saponosides and terpenoids in the fractions, which block the action of ACh. Indeed, these compounds are known for their anti-diarrhoeal properties through their spasmodic effects. Moreover, these results are in agreement with the literature, which has documented the anti-diarrhoeal effects of a decoction of D. mespiliformis leaves, traditionally used in Ghana and Nigeria. Preliminary results with the freeze-dried aqueous decoctate of the plant’s leaves not documented in the present work also showed spasmodic effects on isolated rat duodenum. More effective than RAF but weaker than EAF. The cytoplasmic increase in Ca²⁺ concentration in smooth muscle cells is the main stimulus for contraction, which usually results from both intracellular release of stored Ca²⁺ and influx of extracellular Ca²⁺. The concentration-dependent spasmodic effect of RAF and RAF on contractile activity in the isolated gut could be the result of Ca²⁺ uptake by phosphorylated proteins under the influence of cAMP-activated protein kinase. It may also be due to an inhibition of calcium influx or an increase in calcium efflux without altering influx, causing gastrointestinal smooth muscle relaxation. In addition, RAF and RAF inhibit BaCl₂-induced smooth muscle contraction. Indeed, both fractions at concentrations of 0.03-10 mg/mL induced a relaxant effect on the rat duodenum by significantly and concentration-dependently reducing contractions. This effect could be due to an action similar to papaverine with a musculotropic effect, by inhibiting phosphodiesterase function. However, the mechanism of action of these fractions needs to be studied in greater depth, especially the assessment of their in vivo anti-diarrhoeal properties and their medium- and long-term oral toxicity.

CONCLUSION

We are not aware of any work on the spasmodic properties of Diospyros mespiliformis leaves fractions. Results have shown that ethyl acetate and residual aqueous fractions of Diospyros mespiliformis leaves inhibit the contractile actions of intestinal muscle by ACh and BaCl₂. These effects are thought to be mediated by tannins, saponosides, flavonoids, sterols and terpenoids, which also have antioxidant and anti-inflammatory effects. The ethyl acetate fraction was moderately toxic at high doses compared to the residual aqueous fraction. Thus, the present study contributes to new knowledge of the spasmodic effects of Diospyros mespiliformis leaves on the isolated rat duodenum, and reinforces the traditional use of this plant for gastrointestinal symptoms. However, further research is needed to improve our understanding of the mechanisms involved.
